LSU C4G Best Practice Videos are available on YouTube
youtube.com/user/LSUC4G

Topics you will find include the following and much more...

Determining Elevations with GNSS
- Coastal Issues Facing Southeast Coastal Louisiana What to Do? (Tim Osborn, NOAA)
- Subsidence in the Gulf Coast (Dr. R. Dokka, LSU)
- Vertical geodetic control in southern Louisiana: Providing the National Spatial Reference System in dynamic regions (Ms. R. Shields, NGS)
- Introduction to GNSS (Mr. C. Mugnier, LSU)
- Guidelines for establishing GPS-derived ellipsoid heights: NGS Technical Publication 58 (Mr. D. Zilkoski, Director Emeritus, NGS)
- Guidelines for establishing GPS-derived orthometric heights: NGS Technical Publication 59 (Mr. D. Zilkoski, Director Emeritus, NGS)
- Improvements to the Geoid model (Dr. G. Mader, NGS)
- OPUS products (Dr. M. Schenewerk, NGS)

Real-time Kinematic Surveying and Best Practices
- RTK best practices (Mr. W. Henning, NGS)
- Introduction to Real-time GNSS networks (Dr. R. Dokka, LSU)
- NGS support for Real-time networks (Mr. W. Henning, NGS)

Information provided in this document is intended as a guide only and its accuracy is not guaranteed.
What is a CORS?

Most people are now familiar with the use of Global Navigation Satellite Systems (GNSS) like the ones used for in-car and handheld navigation. They calculate position using signals from GNSS, such as the United States’ Global Positioning System (GPS), and have an accuracy of somewhere between a few and several tens of meters. This is the result of minute errors in the satellite orbits, the clocks installed in the satellites and receivers, as well as the tendency for the earth’s atmosphere to bend or delay the GNSS radio signal. There are, however, GNSS receivers used by surveyors and researchers which can be used to accurately calculate position at the centimeter level. To obtain this accuracy these receivers and associated software need to be able to include sophisticated error corrections in their position calculations.

A Continuously Operating Reference Station “CORS” is a high precision GNSS antenna/receiver set on a stable monument. While continuously logging position data, the CORS are used to generate the information needed by high precision GNSS receivers for error corrections in real-time or post processing.

How GULFNet became C4Gnet

LSU Center for GeoInformatics (C4G) was created by founding director Dr. Roy K. Dokka & LSU’s College of Engineering in 2001, C4G became the home of Louisiana Spatial Reference Center (LSRC), in 2002 through a partnership with NGS-NOAA to create a CORS infrastructure across the state of Louisiana. These CORS provided the positional infrastructure needed for a state-of-the-art active control network that C4G used to re-establish the National Spatial Reference System (NSRS) within the state as defined and managed by the National Geodetic Survey (NGS). In 2007 C4G launched a Real-time Network (RTN) utilizing LSRC’s state-wide active control networks’ GPS CORS infrastructure and called it GULFNet. GULFNet was based on a constrained adjustment of a prior NGS reference frame NAD 83 (CORS96) Position (Epoch 2002.0) which was the basis for the NAD 83(2007) adjustment. NGS stopped supporting this reference frame on July 15th, 2012. In anticipation of the reference frame change, C4G launched a second RTN named C4Gnet, running on a newer infrastructure software and a constrained adjustment to the coming NGS reference frame. This allowed users to work in either reference frame by logging into GULFNet or C4Gnet. Once NGS stopped support for the prior (CORS96) reference frame, C4G took the GULFNet RTN offline and reconfigured equipment to become redundant servers for the C4Gnet RTN, and all GULFNet RTN clients were switched over to the C4Gnet RTN on or before July 15th, 2012. C4Gnet RTN data are always based on the current NGS CORS reference frame coordinates which are presently NAD 83(2011) Position (Epoch 2010.00) adjustment. The C4Gnet RTN currently runs on Trimble’s Pivot Platform which supports multiple reference frames within the infrastructure software making transitions to future reference frames simple and painless for everyone.

RTX Technology

The RTX Technology infrastructure is a unified framework for estimating satellite parameters for any GNSS satellite. Trimble RTX Technology is revolutionizing global access to high accuracy positioning by creating a system using a worldwide GNSS network to estimate centimeter level real-time satellite orbit and clock corrections and delivers them to any point on earth via satellite broadcast or the Internet. Using multiple network operations centers and redundant communication links, RTX Technology’s infrastructure ensures the availability of corrections to users across the globe. GNSS field receivers use advanced Precise Point Positioning (PPP) processing algorithms to combine RTX corrections with local measurements and produce cm-level accurate absolute positions. RTX corrections are used in a variety of real-time and post-processed positioning applications. RTX based precise absolute positioning is especially useful in remote regions or for coordinate monitoring in locations subject to seismic or subsidence activity.

RTXNet Processor

RTX Technology enables the RTXNet Processor to develop corrections for a full range of satellite systems and delivers Network-RTK corrections for GPS, GLONASS, BeiDou, Galileo, and QZSS. Complete GNSS Network-RTK corrections are available in the industry standard RTCM 3.2 format, Trimble’s CMRx format, or the CMR format. Trimble’s RTX Technology also improves robustness when working with weak satellite signal transmission or reception and reduces the time to identify and respond to satellite system or signal integrity issues, allowing the delivery of the most complete, reliable, and accurate corrections possible to users. The RTXNet Processor enables real-time network operators to manage stable, highly reliable networks of virtually any size with full multi-GNSS support, now and in the future.

The RTXNet Processor uses satellite corrections to perform independent processing of reference station data. During processing, additional corrections are applied to measurements, including satellite code bias calibrations, corrections for the yaw angle of the satellite antenna, phase wind-up in the signal path, and the effect of the pole tide. Geometric and ionospheric error models used in Network-RTK corrections are derived from processed observation residuals. This new processing architecture significantly reduces server CPU loading. The RTXNet processing technique also results in increased tolerance for varying station spacing. This allows data from regions with dense station spacing to be processed with data from regions with wider spacing and even allows a single network processor to handle two or more separate networks. The ability to process very large or mixed geometry networks in Network-RTK mode on a single server and deliver full range real-time GNSS network modeled RTK corrections is unmatched in the industry. This allows very large networks or a combination of networks to be processed by a single module on one server with full GNSS correction support.
Here you can chose to download the data or send it via email. Please be aware that the data files are quite large and may be blocked by email systems. You also have the choice of downloading the data in a number of formats. These are RINEX 2.11, RINEX 3.0, DAT, TGD, T01 and T02. While the RINEX formats should be recognized by most software packages, the last four options are not international standards but may be of use to some users. When your delivery options selection is complete click Next: Generate Data >>.

A table indicating the Processing Status of the order will appear. You can close this screen and the data generation will still continue. For large orders it may be preferable to return at a later time to retrieve the data once this generation is complete. Once the data generation is complete, click on Next: Order Details >>.

Here you will see a summary of the order including the completeness of the data. Select an order item and click on Details to see further information. Click on Remove to delete an order item from the list. Click on Download or Send by e-mail to retrieve the data.

The data will be delivered in a compressed zip file. Within the zip file you will find three RINEX files: the observation file and navigation files for each station-session chosen. You will also find a text file which summarizes the data ordered including the completeness of the data.

Atmospheric Conditions

This tool will let you see the current and historical weather conditions at any station in the RTN. This tool currently tracks Integrated Precipitable Water Vapor and Total Electron Content. If you need to see how the weather conditions may have impacted data you collected, this is a good place to find out what was happening anywhere our coverage area.

The RTXNet Processor incorporates RTX Technology as the core of a Network-RTK solution that supports the expanding range of GNSS systems and signals while at the same time reducing the network processing CPU load. Our new RTXNet Processors deliver the next generation of real-time GNSS network modeling taking full use of all available GNSS signals, i.e. - GPS, GLONASS, Galileo, BeiDou and QZSS. Rovers connected to mountpoints using RTXNet-based processors are sent corrections based on advanced Precise Point Positioning (PPP) processing algorithms to combine RTX corrections with local measurements and produce cm-level accurate absolute positions.

As illustrated above, our RTXNet Processors currently deliver additional satellites from Galileo and BeiDou in solutions sent to rovers connecting to our new PPP mountpoints in the formats of CMRx or RTCM 3.2 Multi-Signal Message (MSM). Rovers wishing to take advantage of these additional SV’s need to connect to a PPP mountpoint that delivers corrections in CMRx or RTCM 3.2 Multi-Signal Message (MSM) format.

Using a PPP mountpoint also gives your rover a second real-time processing method to collect data. By taking a point with a PPP mountpoint and then with a VRS mountpoint, you can compare these positions as a way to check data collected within real-time! If data collected with both PPP and RTK agree, you have a very high confidence that the data collected is accurate.

Please Note: VRS RTK mountpoints only support GPS and GLONASS constellations currently, only our PPP mountpoints in CMRx or RTCM 3.2 MSM formats currently have the ability to support GPS, GLONASS, Galileo and BeiDou satellite constellations.

C4Gnet.XYZ Web Portal Features

Log into the C4Gnet.XYZ Web Portal to access the following tools that help clients interact with C4Gnet.XYZ services.

Positioning Tools:

- GNSS Online Post Processing (OPP)
- VRS iScope and iScope Live!
- Real Time RTXNet Processor using Precise Point Positioning (PPP)
- New Mountpoints and a new mountpoint naming convention
- Atmospheric Conditions Monitoring Tools
Online Post Processing (OPP)

C4Gnet GNSS Online Post Processing is an OPUS-like online post processing service that allows you to upload raw static GNSS observation data and receive absolute positioning calculations based on reference stations in the C4Gnet network. Note that the C4Gnet GNSS Online Post Processing service uses GPS, GLONASS, Galileo and BeiDou satellite data and has access to all of the LSRC CORS network of over 100 reference stations, whereas the NGS OPUS tool is limited to only 31 LSRC CORS reference stations.

Supported data formats are RINEX 2.xx, RINEX 3.xx, Hatanaka-compressed RINEX files and Trimble proprietary data formats (DAT, TGD, T01 and T02).

Data files must be a minimum of 10 minutes of static only (no kinematic) and data files must contain dual frequency pseudorange and carrier phase observations (L1 and L2).

If your observation data consists of several files from the same station, please compress them to a ZIP archive and upload the zipped file. All files inside the archive must belong to the same station and have identical header information regarding receiver type and antenna type as these are read from your file and entered automatically and will appear in the order solution report.

The user interface is quite simple, just hit the Browse button and select a file to upload, enter your email address and hit Submit. If you hit the My Orders link in the header menu you will find a list of your Orders in Progress and Processed Orders. The C4Gnet GNSS OPP system automatically sends notices with links to the solutions to the email you entered when submitting the order but links to the XDF and PDF copies of the reports can be found under your My Orders listings.

Solution datums are NAD83-2011 @ epoch 2010.00 and include Ellipsoidal and Orthometric heights, X, Y, Z and Lat/Lon. NAVD88 and GEOID18 (Conus) are used for the Orthometric heights.

Select the date, start time, duration and interval. Please note that the time system used is GPS time and not a standard zone such as Central Standard Time. You will need to add 6 hours to Central Standard Time (or five hours to Daylight Savings Time) to determine the appropriate GPS time.

Once your Time Selection details are complete click Next: Add to order >.

Here you can either select to add additional order items through a number of options. Ensure you book the order under your primary login as real-time logins do not have access to Reference Data Shop data. Note: Data is Unlimited, so no additional fees apply.

Once your order is complete, click Next: Delivery Options >>.
Status Messages

Status messages are used to inform users of important information about C4Gnet RTN. Three levels of messages exist: **Info, Warning** and **Alert**. These will be highlighted **green, yellow and red** respectively to indicate the severity of the message. **Info** messages will be used to inform users of general news and tips for using C4Gnet RTN. **Warning** messages will be used to inform users of planned maintenance and any issues associated with C4Gnet RTN. **Alert** messages will be used for major issues and unplanned outages of service.

Users are advised to subscribe to the RSS feed to ensure that they keep up to date with the latest information available. This feed can be accessed by some mobile phones in the field.

Reference Data Shop

This is where you can access archived GNSS data as RINEX files or alternatively in a number of other formats in whatever durations and interval you desire.

The first time you access the Reference Data Shop you will be asked to start a new order. After that you will be given the option of choosing to **View/submit order, Add order items or Cancel** order. You can also view a list of orders not yet downloaded and already downloaded orders. When ordering data you are given the option of ordering **Continuously Operating Reference Station (CORS) data** or **Virtual Reference Station (VRS) data**. CORS data is the data observed at the CORS sites while VRS data is virtual data generated for a user specified location.

When selecting the **Reference Stations** for which you would like to download data, you can either select one or many stations from the list or select them by clicking on the map.

Once your selection is complete, click **Next: Time Selection >>**

![C4Gnet GNSS Online Post Processing Report Layout](Image)
VRS iScope and iScope Live!

If you manage multiple field crew rover accounts the new VRS iScope Live! service provides an interactive map that can be used to view the location of your rovers that are currently logged into the RTN and receiving corrections.

VRS iScope service provides a remotely accessible interactive map that shows recent rover sessions for each rover account and the current activity or the trajectory of recent sessions; making it easy for field crew managers to schedule, track, and manage projects more efficiently. These iScope tools are a great way for managers in the office to keep up with their connected rovers in the field and review previous survey sessions for each rover account.

If you would like VRS iScope and iScope Live! added to your account, contact C4G by email and we will setup your accounts to access these rover monitoring tools.

Real Time RTXnet Processor using Precise Point Positioning (PPP)

Rovers can access the New RTXnet processors for their real-time data solutions using one of our New PPP mountpoints. These PPP mountpoints give rovers a second real-time method to collect data and/or to use as a real-time method of checking data collected with the real-time VRS RTK mountpoints. If data collected with both PPP and VRS agree, you will have a very high confidence that the data collected is accurate. Also while VRS mountpoints currently only support GPS and GLONASS constellations, C4Gnet’s PPP CMRx and RTCM3.2 mountpoints currently support GPS, GLONASS, Galileo and BeiDou satellite constellations and are ready for other constellations if or when they are available in our coverage area. The additional constellations help with quicker initialization times and add additional satellites when rovers are in urban canyons or under canopy.

Note: Check with your GPS dealer to see if your rover is Galileo/BeiDou-ready in order for you to take full advantage of these additional Galileo and BeiDou satellites.

195 Ionosphere

The 195 ionosphere link takes you to the Index 95 charts that reflect the intensity of ionospheric activity, i.e., the expected influences onto the relative GPS positions. Both current and historical 195 activity are available.

IRIM/GRIM 95

The IRIM/GRIM link takes you to charts of the current predicted and historical ionospheric and geometric errors. IRIM is Ionospheric Residual Integrity Monitoring, GRIM is Geometric Residual Integrity Monitoring.

Under disturbed ionospheric condition, ionospheric residuals can not be considered as linear. The Network Processor module also describes the potential non-linear residual errors in the generated data stream transmitted to the user. This can also be considered as integrity monitoring for residual interpolation and ambiguity resolution in the network. It is a very useful tool to predict the rover performance. The C4Gnet Web Portal is the best way to find the current and historical predicted ionospheric and geometric errors. C4Gnet removes the linear parts of these effects by applying ionospheric and geometric corrections to the raw data.
**Sensor Environment**

The Sensor Map link takes you to a dynamic map of all C4Gnet.XYZ RTN CORS stations. You can come here to check on the status of the network. The sensor map uses the OpenStreetMap application to visualize the location and health status of the sensors (GNSS Receivers) to users. C4Gnet subscribers can click on the sensor symbols to see more information such as Station Overviews and other detailed reporting.

**Position Scatter Plot**

The Position Scatter Plot link takes you to a dynamic scatter plot of the station selected. This interactive tool lets you check in the 2D position of a station over a period of time that you set.

---

**C4Gnet RTN Rover Users Guide**

**How to Log-in to the NTRIP caster for real-time corrections**

Registered users with active Subscriptions will be able to log in to the C4Gnet.XYZ NTRIP caster for real-time corrections for their field rovers using the following information in their NTRIP client settings:

- **Host Address:** C4Gnet.XYZ
  - (If your rover will not accept a DNS for the host address, call 225 578-4609 or email rosbor1@lsu.edu for the current IP address. Note that using the direct IP address will disable the automatic failover feature therefore using DNS is preferable.)
- **Port Address:** 9000

Once connected to the NTRIP caster your rover can request a list of available mountpoints.

**What are Mountpoints?**

A mountpoint defines the type of processor used, what satellite constellations are supported, the format of the correction messages and the reference frame that relates to a real-time data stream. When connecting to the C4Gnet Real Time Network, a mountpoint list is generated from which a user selects the desired mountpoint. If a mountpoint is hard coded in a rover setup the mountpoint list will not be displayed.

**NOTE:** All mountpoints except the legacy ones use this naming structure:

```
TYPE_SATS_FORMAT_REFERENCE FRAME
```

Also Note: The Legacy mountpoint names are obsolete!

Since legacy mountpoints like GLN_RTCM3_2, GLN_CMRx and GLN_NetDGPS do not follow the new naming convention, it was hard to know what is being provided in their solutions. Therefore, some have been removed from the mountpoint list already and others will be removed soon.

If you currently use a legacy mountpoint, you must change to one of the new mountpoints using the new naming convention. While legacy mountpoints will work for a short while the same as the new ones, you will have to figure out what each one contains after connecting to it and since it will be removed soon, we recommend that you do not use them anymore and move to a new mountpoints ASAP.

Like with all Global Navigation Satellite System-based positioning, C4Gnet RTN is related to orthometric datums like NAVD88 by way of a geoid model or through a local network adjustment; the latter is accomplished by including and holding fixed several NGS benchmarks with valid coordinates. C4Gnet RTN data are based on coordinates in IGS08 epoch 2005.00 and NAD 83(2011) Position (Epoch 2010.00) adjustment.

**Using C4Gnet RTN in Real-time**

Live station status, coordinates & the current network solution coverage area are available on the C4Gnet.XYZ web portal by selecting the Sensor Map link from the left hand menu or by directing your browser to this address: http://C4Gnet.XYZ/Map/SensorMap.aspx.

You can also manage your real-time rover login passwords, get rover session details and update your personal data when logged into the C4Gnet RTN Web Portal. All of these options are located under the My Account menu item.

Real-time rover logins are in the format of **username** and **password** while web portal logins require **organization**, **username** and **password**. The number of concurrent real-time rover logins will depend on the number of subscriptions licensed by you.
PPP Mountpoints and Mountpoint Naming Convention for the C4Gnet.XYZ RTN

In order to differentiate between traditional VRS RTK solutions, Precise Point Positioning (PPP) RTX RTK solutions and Nearest Single Base RTK, we have added additional mountpoints to our RTN. Most mountpoints follow a naming structure that lets you know the solution type, satellite constellation(s), message format and reference frame that each mountpoint is using. Once you understand this naming structure you can easily choose any mountpoint and know exactly what kind of solutions are being sent to your rover.

New Mountpoint Naming Convention uses 4 Groupings:

1. The first set of characters is the SOLUTION TYPE. VRS, PPP or NSB are the current processing methods that you can choose:
   - **VRS** or Virtual Reference Station: Uses a Network RTK Processor to create a Virtual Reference Station and applies network corrections in RTX accuracy from the parent processor to the receiver data.
   - **PPP** or Precise Point Positioning: Uses a Network RTKXNet Processor to create a Virtual Reference Station and applies network corrections in RTX accuracy from the parent processor to the receiver data.
   - **NSB** or Nearest Single Base: Selects the nearest suitably operating reference station using the position reported by the rover and propagates that receiver’s observation data to the rover.

2. The second set of characters points out the SATELLITES:
   - **GPS**: Mountpoints with GPS in the name use GPS satellite vehicles only.
   - **GNSS**: Mountpoints with GNSS in the name use both GPS and GLONASS SVs in the solutions.
   - **GPS**: Mountpoints with GPS in the name use GPS satellite vehicles only.
   - **GNSS**: Mountpoints with GNSS in the name use both GPS and GLONASS Satellite Vehicles in their solutions. Mountpoints with GREC in the name only appear in mountpoints in the CMRx or RTCM3_2 format that use the PPP or NSB processing methods.

3. The next set of characters define the MESSAGE FORMAT.

The following explains each available format:

- **CMRx**: This is the latest Trimble proprietary format for Network RTK mountpoints: CMRx allows Real-Time Kinematic (RTK) users to use more satellite constellations and signals as they become available, with faster initializations and improved performance near obstructions and under canopies. It offers significant compression (around 40%) over the already compact CMR/CMR+ format to help users receive corrections within less bandwidth. Trimble rovers that support CMRx should use it exclusively.
- **RTCM 3.2**: Carrier and Code Differential Corrections for High-Precision RTK, Network RTK, and PPP-type applications. Recently modernized with so-called Multiple Signal Messages (MSM), for generic inclusion of new constellations and signals. MSM currently supports GPS, GLONASS, Galileo, GLN, BeiDou, SBAS.
- **CMR+**: Network RTK mountpoint (e.g., CMRx_NODE_1): This is intended for legacy equipment in industry groups where CMRx plus has been used as a quasi-standard format (such as precision agriculture). CMRx plus is a Trimble format so non-Triple users are advised to use the RTCM 3.x format unless you are sure your device fully supports CMRx.
- **RTCM 3.1**: Network RTX mountpoint (e.g., CMRx_GREC_1): This format supports both GPS and GLONASS SVs and will supply a network RTX data stream optimized for the user’s location.
- **DGPS**: Virtual Base mountpoint (e.g., NetDGPS_1): This will supply a sub-meter differential solution optimized for the user’s location.

4. The fourth and last set of characters is the REFERENCE FRAME e.g.: NAD83 or ITRF2014.

NAD83 and ITRF2014 are different reference frames, and we call them out in the mountpoint name so that users may tell them apart by simply looking at the mountpoint names. C4Gnet.XYZ can support any reference frame users need to work in so if or when we get requests for additional reference frames or when a new datum is published by National Geodetic Survey (NGS), we can add these and make them easy to select by looking at the reference frame being used at the end of each mountpoint name.

Recommended Survey Mountpoints:
- Trimble Rovers – **PPP_GREC_CMRx_NAD83**
- Other Rovers – **PPP_GREC_RTCM3_2_NAD83**

**NOTE:** We encourage you to try other mountpoints if you are not getting the expected precisions or number of SV’s.
The Sensor Map link takes you to a dynamic map of all C4Gnet RTN CORS stations. You can come here to check on the status of the network.

The public map is interactive and by clicking a station, you will get a pop-up bubble that lets anyone see station information such as station health, RTN health, station name, location, code, ID, Lat, Lon, height and type of receiver.

Additional information will also be available to subscribers once they have successfully logged into the C4Gnet.XYZ Web Portal.

The messages used in each mountpoint can be found by directing your browser to C4Gnet.XYZ:9000 where you will see a source table like the following:

**MOUNTPOINT SOURCE TABLE**

The Sensor Map

The webpage for C4Gnet RTN is available at the following URL: http://C4Gnet.XYZ

Logged Out Environment

Sensor Map

The Sensor Map link takes you to a dynamic map of all C4Gnet RTN CORS stations. You can come here to check on the status of the network.

The public map is interactive and by clicking a station, you will get a pop-up bubble that lets anyone see station information such as station health, RTN health, station name, location, code, ID, Lat, Lon, height and type of receiver.

Additional information will also be available to subscribers once they have successfully logged into the C4Gnet.XYZ Web Portal.

The messages used in each mountpoint can be found by directing your browser to C4Gnet.XYZ:9000 where you will see a source table like the following:

**MOUNTPOINT SOURCE TABLE**

<table>
<thead>
<tr>
<th>MOUNTPOINT</th>

Network Real-time Solutions

GNSS Network solutions are available throughout the state of Louisiana and the network density will continue to increase as C4G/LSRC rolls out new CORS across the state and replaces current CORS with Multi-Constellation CORS. For those who have not used a network solution before, they will look and feel, in a practical sense, like single base solutions. Field procedures should remain the same, particularly in relation to performing site calibrations (localizations).

GPS is based on an Earth Centered Earth Fixed 3-D reference frame, so local vertical is not a product of GPS. Therefore, C4Gnet RTN corrections are not directly connected to NAVD 88. The user must determine the appropriate adjustment to local vertical datums, including NAVD 88. Most often this is accomplished by means of a recent geoid model, the current one being GEOID18. GEOID18 is intended for use with coordinates in the North American Datum of 1983 (2011) [NAD 83 (2011) epoch 2010.00]. It provides orthometric heights consistent with the North American Vertical Datum of 1988 (NAVD 88).

In areas tested to date, network solutions perform as well or better than single base solutions. It is important to ensure that your equipment settings match the particular mountpoint you intend to use.

Antenna Settings in C4Gnet

Please be advised that the Trimble Infrastructure software being used by C4Gnet RTN will adjust real-time data so that all CORS antennas are uniformly described as a null antenna (ADVNULLANTENNA). As such, no base station antenna model needs to be applied to adjust CORS observations from the Antenna Phase Centre to the Antenna Reference Point. Users will still need to apply the appropriate absolute antenna model for their rover.

Absolute antenna modeling, (instead of relative antenna modeling), is used in the infrastructure management software used by C4Gnet RTN. These should be the absolute antenna models developed by the International GNSS Service (IGS) and users are advised to contact their local GNSS supplier for the required information. Users should also use absolute antenna models when post processing for both the user and CORS antennas. Any mix of absolute and relative antenna modeling will introduce significant systematic errors.

All post process RINEX files and post process files in other formats will continue to hold raw data to the Antenna Phase Center, in line with international standards.

Always Check Your Work

Precision is dependent upon equipment and procedures. Accuracy should be checked relative to a known or assumed standard. C4G constrains its RTN to the currently published NGS NSRS reference frame.

Rovers wanting to check RTN data collected with C4Gnet, typically compare RTN RTK (VRS) positions to static GPS positions in a Post Processing tool like (OPUS) or C4G’s New GNSS Online Post Processing service. While this method works well, it takes some time to do these post processed checks. C4G now offers an entirely new method of doing real-time data collection using RTXnet processors producing Precise Point Positioning (PPP) solutions. These PPP solutions give rovers a second real-time method to collect data and/or use as a real-time method of checking data collected using real-time VRS RTK processed solutions. If data collected with both PPP and VRS agree, you have a very high confidence that the data collected is accurate. For the highest level of confidence, all accuracy assessments should also include connections to realizations of local coordinate systems and datums.

Network RTK Best Practice Procedures:

I. Be In The Box: Users should be aware of the Network Boundaries. Best results will be achieved when you work inside the Network Boundaries.

II. Planning: Be aware of satellite geometry as it will have an effect on performance. Well distributed satellites in your sky plot work better than tight groupings of satellites.

III. Observing Control: A minimum of one hundred eighty (180) epochs is recommended with a starting rms <30. For best results, a second set of measurements should be taken no sooner than 45 minutes later. This gap in time is important for the establishment of a different satellite constellation. The measurements need to be made with different satellite geometries. The difference between the two measurements is double the probable error. If it exceeds project requirements, re-observe after a three hour change in satellite geometry. Repeat this method until accuracy meets project requirements. (If repeat measurements are made one after the other you must re-initialize the receiver between measurements.)

IV. Observing Topo: One five (5) second measurement with an rms <30. If initialization is lost due to high rms, measurements within that initialization should be checked.

V. Site Calibration: A site calibration fits the measurements to local control. Errors in the control will change the observed values. In most cases the reported values will provide the best fit to local control.
